FIG. S1. (a) Side view of phosphorene oxide (PO) and (b) a simple quasi one-dimensional model structure corresponding to PO. Masses m_1 and m_2 represent phosphorous and oxygen atoms, respectively, and the spring constants k , k' and k'' do the P–P, P–O, and O–O bonds, respectively. In the limit of $k'' \rightarrow 0$, m_2 may be mapped into the “flexible” oxygen atom in PO. The box depicts the s -th unit cell with the lattice constant a of the mode structure. To simplify the model calculation, we only allowed m_1 and m_2 to move horizontally.

To investigate the role of the “flexible” oxygen atom in PO, we devised the model structure composed of two masses m_1 and m_2 connected with three different types of springs k , k' , k'' as shown in Fig. S1. With the generalized coordinates u_s and v_s assigned to the displacements of the s -th m_1 and m_2 , the equation of motion is given by

$$m_1 \frac{d^2 u_s}{dt^2} = k(u_{s+1} + u_{s-1} - 2u_s) - k'(u_s - v_s) \quad (\text{S1})$$

$$m_2 \frac{d^2 v_s}{dt^2} = k''(v_{s+1} + v_{s-1} - 2v_s) + k'(u_s - v_s). \quad (\text{S2})$$

We look for a traveling wave solution with different amplitudes u and v ,

$$u_s = u e^{i s q a} e^{-i \omega t}, \quad v_s = v e^{i s q a} e^{-i \omega t}.$$

Thus, Eqs. (S1) and (S2) become

$$\begin{aligned} -m_1 \omega^2 u &= k(e^{i q a} + e^{-i q a} - 2)u - k'(u - v) \\ -m_2 \omega^2 v &= k''(e^{i q a} + e^{-i q a} - 2)v + k'(u - v). \end{aligned}$$

These coupled equations can be solved by setting the determinant to be zero, or

$$m_1 m_2 \omega^4 + \omega^2 \left\{ -4(m_2 k + m_1 k'') \sin^2 \left(\frac{qa}{2} \right) - k'(m_1 + m_2) \right\} + 16k k'' \sin^4 \left(\frac{qa}{2} \right) + 4k'(k + k'') \sin^2 \left(\frac{qa}{2} \right) = 0,$$

and thus the two solutions are

$$\begin{aligned} \omega_{\pm}^2 &= 2 \left(\frac{k}{m_1} + \frac{k''}{m_2} \right) \sin^2 \left(\frac{qa}{2} \right) + \frac{k'}{2} \left(\frac{1}{m_1} + \frac{1}{m_2} \right) \\ &\pm \sqrt{4 \left(\frac{k}{m_1} - \frac{k''}{m_2} \right)^2 \sin^4 \left(\frac{qa}{2} \right) + \frac{k'^2}{4} \left(\frac{1}{m_1} + \frac{1}{m_2} \right)^2 + 2k' \sin^2 \left(\frac{qa}{2} \right) \left(\frac{k}{m_1^2} + \frac{k''}{m_2^2} - \frac{k + k''}{m_1 m_2} \right)} \end{aligned} \quad (\text{S3})$$

These solution can be confirmed in a special condition of $m_1 = m_2 = m$ to be

$$\omega_{\pm}^2 = \frac{1}{m} \left[2(k + k'') \sin^2 \left(\frac{qa}{2} \right) + k' \pm \sqrt{4(k - k'')^2 \sin^4 \left(\frac{qa}{2} \right) + k'^2} \right],$$

and further to be, when $k'' = k$,

$$\omega_{\pm}^2 = \frac{1}{m} \left[4k \sin^2 \left(\frac{qa}{2} \right) + k' \pm k' \right].$$

The lower solution ω_- simply corresponds to the acoustic phonon branch of the monatomic chain system.

To understand role of the flexible oxygen atom corresponding to m_2 and k'' , we plotted the phonon dispersion relations of our model system with various parameters shown in Fig. S2. As clearly seen in the figure, the smaller k'' , the lower the acoustic phonon frequency. Thus, the flexibility of oxygen atoms in PO may lead to the softening of acoustic phonon modes resulting in the reduction in thermal conductivity.
